Preface

The Bioconductor package iSEE provides functions for creating an interactive graphical user interface (GUI) using the RStudio Shiny package for exploring data stored in SummarizedExperiment objects, including row- and column-level metadata (Rue-Albrecht et al., 2018). In this book we describe how to create web-applications that leverage builtin panels and develop new ones. We also present case studies to illustrate the development of custom panels.

6 CONTENTS

Panel classes

1.1 Overview

The types of panels available to compose an iSEE app are defined as a hierarchy of S4 classes.

```
    Panel*

            DotPlot*
            RedDimPlot
            ColDataPlot
            FeatAssayPlot
            RowDotPlot*

                    RowDataPlot
                    SampAssayPlot
                    Table*

                    RowTable*
                    RowStatTable
                    * ColstatTable
                    HeatMapPlot
```

Some of those classes are "virtual" (indicated by *), meaning that they cannot be directly instanciated as panels in the GUI. Instead, virtual panel classes define families of panels that share groups of properties.

Virtual classes are meant to be used as the parent of one or more concrete classes. In contrast, concrete classes must define fully-functional panels that can be embedded in a GUI, interact with other panels, receive and process data, and generate an output such as a plot or a table, accompanied by a code chunk to display in the code tracker for reproducibility.

1.2 The Panel class

The top-most class is called Panel. It is a virtual class that defines the core properties common to any panel - existing or future - that may be displayed in the interface.

Refer to help("Panel-class") for more information about the slots and methods provided by this core class.

1.3 The DotPlot and Table panel families

The Panel virtual class is directly derived into two major virtual sub-classes:

- DotPlot
- Table

Those classes introduce properties that are specific to distinct subsets of panel types.

The DotPlot class introduces parameters specific to panels where the output is a ggplot object and each row in the data-frame is represented as a point in a plot.

The Table class introduces parameters specific to panels where the main output is a data-frame directly displayed as a table in the GUI.

In addition, the HeatMapPlot class defines a special concrete panel class that directly extends the Panel class, as it introduces a set of parameters distinct from both the DotPlot and Table panel families. This panel type is described in further details in a separate section below.

- 1.4. THE COLUMNDOTPLOT AND ROWDOTPLOT PANEL FAMILIES 9
- 1.4 The ColumnDotPlot and RowDotPlot panel families
- 1.5 Built-in ColumnDotPlot panel classes
- 1.6 Built-in RowDotPlot panel classes
- 1.7 The ColumnTable and RowTable panel families
- 1.8 Built-in ColumnTable panel classes
- 1.9 Built-in RowTable panel classes
- 1.10 The HeatMapPlot panel class

This type of panel introduces parameters specific to panels where the output is a heat map, with each row representing a feature and each column representing a sample in the se object.

The panel API

2.1 .cacheCommonInfo

Each individual panel type (e.g., *Reduced dimension plot*) and family of panel types (e.g., *Column dot plot*) defines a .cacheCommonInfo function.

This function is called for each panel instance in memory when the app is initialized. It allows the app to efficiently compute a single time common information that only depends on the input se object, and may be frequently reused during the runtime of an app.

Following the hierarchy of panel types, each call to the signature takes a panel instance x and the se object, and caches common information relevant to all instances of that panel type in the se object itself, before calling callNextMethod() to invoke the next parent signature.

The top-most signature - for the Panel class - returns the se object that contains all the cached information.

Note that this function only populates the cache for the first panel of each type; it is a no-op if the common cache has already been initialized.

2.2 .refineParameters

Each individual panel type (e.g., *Reduced dimension plot*) and family of panel types (e.g., *Column dot plot*) defines a .refineParameters function.

This function is called for each panel instance in memory when the app is initialized, and also when a new panel is added to the GUI. It inspects the parameters of a given panel instance, and replaces invalid parameters with sensible values for a given se object.

Following the hierarchy of panel types, each call to the signature takes an instance x and the se object, and first calls callNextMethod() to invoke the next parent signature, to refine generic parameters before processing specific ones.

The called signature ultimately returns the updated instance panel x, or NULL if the panel instance is not available for this app.

2.3 .generateDotPlot

Each panel type that derives from the virtual class DotPlot must define - or inherits - the .generateDotPlot method.

This function is called within .renderOutput, which is triggered by observers when the value of the input widgets are changed by users, or when a new panel is added to the GUI.

The .generateDotPlot function has access to the parameters for a given panel instance, and uses information available in the panel evaluation environment to generate and evaluate the plotting commands that ultimately produce the ggplot object to display in the panel.

Refer to the "Generating the ggplot object" section of help(".generateDotPlot") for more information.

The app server

- 3.1 Reactive objects
- 3.2 Persistent (non-reactive) objects
- 3.3 The app memory

The app memory is a list of instances created from available panel classes, which defines the order in which individual panels are displayed in the GUI.

3.4 Initialization of the app server

The app server is initialized as soon as a valid se object is provided. This can be either in the call to iSEE(se) or using the Shiny file upload button in apps that were launched without providing the se arguments, e.g., iSEE().

The initialize_server function takes the se object and the list holding reactive values used to trigger re-rendering of the GUI, as described above.

The very first step invokes the function .sanitize_SE_input on the se object. This function coerces the se to SingleCellExperiment, flattens nested DataFrames, adds row and column names, and removes other non-atomic fields. In addition, it also sanitizes the SingleCellExperiment object by moving internal fields into the column- or row-level metadata, making them visible in the Column statistics table and Row statistics table panels, respectively. The function returns both the sanitized se object that will be used by the app, and the list of R commands that will be displayed in the code tracker for users.

Next, the server invokes the checkColormapCompatibility function. This function takes the se object and the optional colormap provided to iSEE(), and

carries out a number of compatibility checks between the two objects. The function collects a character vector of issue messages that are displayed - if any - as warning messages in GUI during initialization.

Next, the .cacheCommonInfo and .refineParameters are successively invoked on each panel instance initialized in the app memory. As described in a separate section above, the first function precomputes and caches information specific to the se object and frequently used throughout the runtime of the app. The second function ensures that each panel instance is initialized with valid parameters; it replaces any invalid parameters with sensible values for a given se object.

Next, persistent (non-reactive) objects are initialized:

- the app memory (see this section)
- the count of panels of each type, used to assign increasing ID to new panel instances
- the list of commands to display in the code tracker for each panel instance
- the list of data point coordinates selectable in each panel instance¹
- a list of miscellaneous cached information²

 $^{^1\}mathrm{Data}$ points downsampled for rendering speed performance remain selectable, even though they are not visible in the plot.

 $^{^2}$ The plot that contain the legend keys of Heatmap panels is currently cached as miscellaneous information retrieved separately when rendering the GUI.

Developing new panels

First, we need to load the iSEE package for this chapter. This action imports all the builtin panel class definitions, including the virtual class Panel that is the base class for any iSEE panel class.

```
library(iSEE)
```

We also set up an example using our favorite dataset, creating a SingleCellExperiment object with some precomputed dimensionality reduction results.

```
library(scRNAseq)
sce <- ReprocessedAllenData(assays="tophat_counts")

## snapshotDate(): 2019-12-27

## see ?scRNAseq and browseVignettes('scRNAseq') for documentation

## loading from cache

## see ?scRNAseq and browseVignettes('scRNAseq') for documentation

## loading from cache

## see ?scRNAseq and browseVignettes('scRNAseq') for documentation

## loading from cache

library(scater)
sce <- logNormCounts(sce, exprs_values="tophat_counts")
sce <- runPCA(sce, ncomponents=4)
sce <- runTSNE(sce)</pre>
```

4.1 Create a new S4 class

In the chapter Panel classes, we saw how each type of panel is defined as an S4 class, organised in a hierarchy that allows new panel classes to inherit sets of the properties and functionality from parent classes.

Then, developing a new panel type starts with the creation of a new class that inherits from the Panel class.

While it is possible to create a new panel class that directly inherits from the top-most virtual Panel class, this is the most advanced use case that we will describe in a later section.

Instead, new concrete panels classes can be rapidly derived from other concrete parent panel classes, using the inheritance relationships between classes to reuse properties and functionality defined in all of the parent classes.

The choice of a parent class for the new panel depends on the properties that we want that new panel to have. For instance, to create a panel that inherits all the functionality of the *Reduced dimension plot* panel type, we simply define a new class that extends the RedDimPlot class. We call that new class RedDimHexPlot.

```
setClass("RedDimHexPlot", contains="RedDimPlot")
```

4.2 Add a constructor function

At this point, it is possible to create instances of the new panel class already. To facilitate this, new panels should provide a constructor function - named identically to the class - to accept arbitrary arguments controlling the initialization of new panel instances created by the new function.

Here, we define a simple constructor function that passes all incoming arguments to the ${\tt new}$ function as is.

```
RedDimHexPlot <- function(...) {
   new("RedDimHexPlot", ...)
}</pre>
```

At this point, we can already use instances of this new panel class in *iSEE* apps.

```
RedDimHexPlot1 <- RedDimHexPlot()
initial <- list(RedDimHexPlot1)
app <- iSEE(sce, initial = initial)</pre>
```

However, that would not be very exciting as instances of this new panel class would behave exactly like the those of the RedDimPlot class.

```
RedDimHexPlot1 <- RedDimHexPlot()
RedDimPlot1 <- RedDimPlot()
```

```
initial <- list(RedDimHexPlot1, RedDimPlot1)
app <- iSEE(sce, initial = initial)</pre>
```

4.3 Set the panel name in the GUI

The panel class that we created so far also inherited the name of the parent panel class. In other words, instances of both classes are indistinguishable from each other in the GUI.

The name of each panel displayed in the GUI is defined by the .fullName method. To clearly distinguish the new panel class in the GUI, we overwrite this method to display a name different from the parent class.

```
setMethod(".fullName", "RedDimHexPlot", function(x) "Reduced dimension hexagonal plot")
```

With that, running app again now highlights how panels of the new class now display a different title from the parent class.

4.4 Define the commands generating a plot output

Importantly, the API separates the generation of commands processing data from sce into a data-frame, from the generation of commands producing a ggplot object using the processed data-frame. If a new DotPlot panel class is meant to process data in the same way as its parent panel, only to display in a different way, it is then possible to overwrite only the .generateDotPlot method.

Importantly, the .generateDotPlot method requires two key arguments: labels provides the plot labels for each of the aesthetics in the plot data, and envir provides the environment in which the plotting commands are to be evaluated to produce the ggplot object.

In particular, .generateDotPlot can rely on certain environment variables promised by the contract. Above all, those include plot.data, the data-frame that contains one row per data point to display. Using those environment variables, .generateDotPlot can make decisions altering the plotting commands and the resulting ggplot object.

We invite readers to refer to the "Generating the ggplot object" section of help(".generateDotPlot") for more information.

As an example, we overwrite the .generateDotPlot function for the new RedDimHexPlot class to simply show the number of data point in the plotting area as a heatmap dividing the plane into regular hexagons. Notably, the function can immediately rely on the plot.data data-frame that is computed

by methods defined for the parent class RedDimPlot. We also use the precomputed aesthetic labels associated with each column of plot.data, while setting a fixed "Count" label for the fill aesthetic associated with the count of observation in each hexagonal bin.

```
setMethod(".generateDotPlot", "RedDimHexPlot", function(x, labels, envir) {
    print(labels)
    stopifnot(require(ggplot2))
    plot_cmds <- list()</pre>
    plot_cmds[["ggplot"]] <- "ggplot() +"</pre>
    # Adding hexbins to the plot.
    plot_cmds[["hex"]] <- "geom_hex(aes(X, Y), plot.data) +"</pre>
    plot_cmds[["labs"]] <- "labs(fill='Count') +"</pre>
    plot_cmds[["labs"]] <- sprintf(</pre>
         "labs(x='\%s', y='\%s', title='\%s', fill='\%s') +",
        labels$X, labels$Y, labels$title, "Count"
    plot_cmds[["theme_base"]] <- "theme_bw() +"</pre>
    plot_cmds[["theme_legend"]] <- "theme(legend.position = 'bottom')"</pre>
    gg_plot <- eval(parse(text=plot_cmds), envir)</pre>
    list(plot=gg_plot, commands=plot_cmds)
})
```

Running app again highlights how the RedDimHexPlot panel fills each hexagonal bin with a color indicating the number of data points present in the corresponding area in the RedDimPlot panel.

Case study I

5.1 Overview

In this case study, we will create a custom panel class to regenerate sample-level PCA coordinates using only a subset of points transmitted as a multiple column selection from another panel. We call this a **dynamic reduced dimension plot**, as it is dynamically recomputing the dimensionality reduction results rather than using pre-computed values in the reducedDims() slot of a SingleCellExperiment object.

5.2 Class basics

First, we define the basics of our new Panel class. As our new class will be showing each sample as a point, we inherit from the ColumnDotPlot virtual class. This automatically gives us access to all the functionality promised in the contract, including interface elements and observers to handle multiple selections and respond to aesthetic parameters.

We add a slot specifying the type of dimensionality reduction result and the number of highly variable genes to use. Any new slots should also come with validity methods, as shown below.

```
library(S4Vectors)
setValidity2("DynRedDimPlot", function(object) {
   msg <- character(0)

if (length(n <- object[["NGenes"]])!=1L || n < 1L) {</pre>
```

```
msg <- c(msg, "'NGenes' must be a positive integer scalar")</pre>
    }
    if (!isSingleString(val <- object[["Type"]]) ||</pre>
        !val %in% c("PCA", "TSNE", "UMAP"))
    {
        msg <- c(msg, "'Type' must be one of 'TSNE', 'PCA' or 'UMAP'")</pre>
    }
    if (length(msg)) {
        return(msg)
    }
    TRUE
})
## Class "DynRedDimPlot" [in ".GlobalEnv"]

## Class "Panel", by class "ColumnDotPlot", distance 3
It is also worthwhile specializing the initialize() method to provide a default
```

for new parameters:

```
setMethod("initialize", "DynRedDimPlot",
    function(.Object, Type="PCA", NGenes=1000L, ...)
{
    callNextMethod(.Object, Type=Type, NGenes=NGenes, ...)
})
```

5.3 Setting up the interface

The most basic requirement is to define some methods that describe our new panel in the iSEE() interface. This includes defining the full name and desired default color for display purposes:

```
setMethod(".fullName", "DynRedDimPlot", function(x) "Dynamic reduced dimension plot")
setMethod(".panelColor", "DynRedDimPlot", function(x) "#0F0F0F")
```

We also add interface elements to change the result type and the number of genes. This is most easily done by specializing the .defineDataInterface method:

```
library(shiny)
setMethod(".defineDataInterface", "DynRedDimPlot", function(x, se, select_info) {
```

We call .getEncodedName() to obtain a unique name for the current instance of our panel, e.g., DynRedDimPlot1. We then paste0 the name of our panel to the name of any parameter to ensure that the ID is unique to this instance of our panel; otherwise, multiple DynRedDimPlots would override each other. One can imagine this as a poor man's Shiny module.

5.4 Creating the observers

We specialize .createObservers to define some observers to respond to changes in our new interface elements. Note the use of callNextMethod() to ensure that observers of the parent class are also created; this automatically ensures that we can respond to changes in parameters provided by ColumnDotPlot.

```
setMethod(".createObservers", "DynRedDimPlot",
    function(x, se, input, session, pObjects, rObjects)
{
    callNextMethod()
    plot_name <- .getEncodedName(x)</pre>
    # TODO: expose .define_protected_parameter_observers for developer use,
    # which would allow these steps to be a one-liner.
    type_field <- pasteO(plot_name, "_Type")</pre>
    observeEvent(input[[type_field]], {
        previous <- pObjects$memory[[plot_name]][["Type"]]</pre>
        if (identical(previous, input[[type_field]])) {
            return(NULL)
        pObjects$memory[[plot_name]][["Type"]] <- input[[type_field]]</pre>
        .requestCleanUpdate(plot_name, pObjects, rObjects)
    })
    num_field <- pasteO(plot_name, "_NGenes")</pre>
    observeEvent(input[[num field]], {
        previous <- pObjects$memory[[plot_name]][["NGenes"]]</pre>
```

Both the NGenes and Type parameters are what we consider to be "protected" parameters, as changing them will alter the nature of the displayed plot. By using .requestCleanUpdate(), we instruct iSEE() to destroy existing brushes and lassos when these parameters are changed, as brushes/lassos made on the previous plot do not make sense when the coordinates are recomputed.

5.5 Making the plot

When working with a ColumnDotPlot subclass, the easiest way to change plotting content to override the .generateDotPlotData method. This should add a plot.data variable to the envir environment that has columns X and Y and contains one row per column of the original SummarizedExperiment. It should also return a character vector of R commands describing how that plot.data object was constructed. The easiest way to do this is to create a character vector of commands and call eval(parse(text=...), envir=envir) to evaluate them within envir.

```
setMethod(".generateDotPlotData", "DynRedDimPlot", function(x, envir) {
    commands <- character(0)
    if (!exists("col selected", envir=envir, inherits=FALSE)) {
        commands <- c(commands,
            "plot.data <- data.frame(X=numeric(0), Y=numeric(0));")
    } else {
        commands <- c(commands,
            ".chosen <- unique(unlist(col_selected));",
            "set.seed(100000)", # to avoid problems with randomization.
            sprintf(".coords <- scater::calculate%s(se[,.chosen], ntop=%i, ncomponents=2);",</pre>
                x[["Type"]], x[["NGenes"]]),
            "plot.data <- data.frame(.coords, row.names=.chosen);",
            "colnames(plot.data) <- c('X', 'Y');"</pre>
        )
    }
    commands <- c(commands,
        "plot.data <- plot.data[colnames(se),,drop=FALSE];",
        "rownames(plot.data) <- colnames(se);")</pre>
```

We use functions from the *scater* package to do the actual heavy lifting of calculating the dimensionality reduction results. The <code>exists()</code> call will check whether any column selection is being transmitted to this panel; if not, it will just return a <code>plot.data</code> variable that contains all NAs such that an empty plot is created. If <code>col_selected</code> does exist, it contains a list of character vectors specifying the active and saved multiple selections that are being transmitted. In this case, we do not care about the distinctin between active/saved selections so we just take the union of all of them.

Of course, this is not quite the most efficient way to implement a plotting panel that involves recomputation. A better approach would be to cache the x/y coordinates and reuse them if only aesthetic parameters have changed, thus avoiding an unnecessary delay from recomputation. Doing so requires overriding .renderOutput() to take advantage of the cached contents of the plot, so for simplicity, we will not do that here.

5.6 Finishing touches

For this particular panel class, an additional helpful feature is to override .multiSelectionInvalidated. This indicates that any brushes or lassos in our plot should be destroyed when we receive a new column selection. Doing so is the only sensible course of action as the reduced dimension coordinates for one set of samples have no obvious relationship to the coordinates for another set of samples; having old brushes or lassos hanging around would be of no benefit at best, and be misleading at worst.

```
setMethod(".multiSelectionInvalidated", "DynRedDimPlot", function(x) TRUE)
```

5.7 In action

Let's put our new panel to the test. We use the **sce** object, preprocessed in a previous chapter, including some precomputed dimensionality reduction results.

The plan is to create a (fixed) reduced dimension plot that will transmit to our dynamic reduced dimension plot. Setting up the iSEE instance is as easy as:

```
rdp <- RedDimPlot(PanelId=1L)
drdp <- new("DynRedDimPlot", SelectColSource="RedDimPlot1")
app <- iSEE(sce, initial=list(rdp, drdp))</pre>
```

5.7. IN ACTION 25

Brushing at any location in the ${\tt RedDimPlot}$ will trigger dynamically recompution of results in our <code>DynRedDimPlot</code>.

Case study II

6.1 Overview

In this case study, we will create a panel class to dynamically compute differential expression (DE) statistics between the active sample-level selection and the other saved selections from a transmitting panel.

6.2 Class basics

First, we define the basics of our new Panel class. As our new class will be showing each gene as a row, we inherit from the RowTable virtual class. This automatically gives us access to all the functionality promised in the contract, including interface elements and observers to respond to multiple selections. We also add a slot specifying the log-fold change threshold to use in the null hypothesis.

```
library(iSEE)
setClass("DGETable", contains="RowTable", slots=c(LogFC="numeric"))
```

Any new slots should come with validity methods, as shown below.

```
library(S4Vectors)
setValidity2("DGETable", function(object) {
    msg <- character(0)

if (length(val <- object[["LogFC"]])!=1L || val < 0) {
    msg <- c(msg, "'NGenes' must be a non-negative number")
}
if (length(msg)) {
    return(msg)
}</pre>
```

```
TRUE })
```

```
## Class "DGETable" [in ".GlobalEnv"]
##
## Slots:
##
                       LogFC
                                        Selected
## Name:
                                                              Search
## Class:
                     numeric
                                       character
                                                           character
##
## Name:
               SearchColumns
                                         PanelId
                                                         PanelHeight
## Class:
                   character
                                         integer
                                                             integer
##
## Name:
                  PanelWidth
                                   SelectBoxOpen
                                                     SelectRowSource
                                         logical
## Class:
                      integer
                                                           character
##
             SelectColSource
## Name:
                                     DataBoxOpen
                                                       SelectRowType
## Class:
                   character
                                         logical
                                                           character
##
              SelectRowSaved
                                   SelectColType
                                                      SelectColSaved
## Name:
## Class:
                                       character
                                                             integer
                      integer
##
## Name: MultiSelectHistory
## Class:
##
## Extends:
## Class "RowTable", directly
## Class "Table", by class "RowTable", distance 2
## Class "Panel", by class "RowTable", distance 3
```

It is also worthwhile specializing the <code>initialize()</code> method to provide a default for new parameters. We hard-code the <code>SelectColType</code> setting as we want to obtain all multiple selections from the transmitting panel, in order to be able to perform pairwise DE analyses between the various active and saved selections. (By comparison, the default of "Active" will only transmit the current active selection.)

```
setMethod("initialize", "DGETable",
   function(.Object, LogFC=0, ...)
{
   callNextMethod(.Object, LogFC=LogFC, SelectColType="Union", ...)
})
```

6.3 Setting up the interface

The most basic requirement is to define some methods that describe our new panel in the iSEE() interface. This includes defining the full name and desired default color for display purposes:

```
setMethod(".fullName", "DGETable", function(x) "Differential expression table")
setMethod(".panelColor", "DGETable", function(x) "#AAFF00")
```

We also add interface elements to change the result type and the number of genes. This is most easily done by specializing the .defineDataInterface method:

As we discussed before, we paste0 the name of our panel to the name of any parameter to ensure that the ID is unique to this instance of our panel.

6.4 Creating the observers

We specialize .createObservers to define some observers to respond to changes in our new interface elements. Note the use of callNextMethod() to ensure that observers of the parent class are also created; this automatically ensures that we can respond to changes in parameters provided by RowTable.

```
setMethod(".createObservers", "DGETable",
    function(x, se, input, session, pObjects, rObjects)
{
    callNextMethod()

    plot_name <- .getEncodedName(x)

    num_field <- pasteO(plot_name, "_LogFC")
    observeEvent(input[[num_field]], {
        previous <- pObjects$memory[[plot_name]][["LogFC"]]
        if (identical(previous, input[[num_field]])) {
            return(NULL)
        }
        pObjects$memory[[plot_name]][["LogFC"]] <- input[[num_field]]
        .requestUpdate(plot_name, rObjects)</pre>
```

```
})
```

The distinction between protected and unprotected parameters is less important for Tables; as long as the types of the columns do not change between renderings, any column or global selections (i.e., search terms) are usually still sensible.

6.5 Making the table

When working with a RowTable subclass, the easiest way to change plotting content to override the .generateTable method. This is expected to generate a data.frame in the evaluation environment, returning the commands required to do so. In this case, we want to perform one-sided t-tests between the active selection and any number of saved selections. We will use the findMarkers() function from scran to compute the desired statistics. This performs all pairwise comparisons, so is not as efficient as could be, but it will suffice for this demonstration.

```
setMethod(".generateTable", "DGETable", function(x, envir) {
    empty <- "tab <- data.frame(Top=integer(0), p.value=numeric(0), FDR=numeric(0));"</pre>
    if (!exists("col_selected", envir, inherits=FALSE) ||
        length(envir$col selected)<2L ||</pre>
        !"active" %in% names(envir$col_selected))
    {
        commands <- empty
    } else {
        commands <- c(".chosen <- unlist(col_selected);",</pre>
             ".grouping <- rep(names(col_selected), lengths(col_selected));",</pre>
             sprintf(".de.stats <- scran::findMarkers(logcounts(se)[,.chosen],</pre>
    .grouping, direction='up', lfc=%s)", x[["LogFC"]]),
             "tab <- as.data.frame(.de.stats[['active']]);"</pre>
        )
    }
    eval(parse(text=commands), envir=envir)
    list(commands=commands, contents=envir$tab)
})
```

Readers may notice that we prefix internal variables with . in our commands. This ensures that they do not clash with global variables created by <code>iSEE()</code> itself (which is not an issue when running the app, but makes things difficult when the code is reported for tracking purposes).

6.6. IN ACTION 31

6.6 In action

Let's put our new panel to the test. We use the sce object, preprocessed in a previous chapter, including some precomputed dimensionality reduction results.

The plan is to create a (fixed) reduced dimension plot that will transmit to our DGE table. Setting up the iSEE instance is as easy as:

```
rdp <- RedDimPlot(PanelId=1L, SelectBoxOpen=TRUE)
dget <- new("DGETable", SelectColSource="RedDimPlot1")
app <- iSEE(sce, initial=list(rdp, dget))</pre>
```

Brushing (or lassoing) at any location and saving the selection will trigger dynamic recompution of results in our DGETable. We can repeat this with any number of saved selections.
